

Mexico Facing CLIMATE CHANGE

Mexico has set out as an indicative or aspirational target, a reduction of 50% in its greenhouse gas (GHG) emissions by 2050, compared with the volume emitted in 2000. In doing so, Mexico aspires to contribute to a potential stabilization of atmospheric GHG concentrations at a level not exceeding 450 parts per million of carbon dioxide equivalent (CO₂e), compatible with limiting the Earth's average temperature increase to between 2° and 3°C, and a flexible convergence towards global average per capita emissions of 2.8 tons of CO₂e, in 2050.

MITIGATION GOALS 2008-2012:

Full implementation of the Special Climate Change Program could achieve a reduction of around 51 million tons of CO₂e in total annual emissions in 2012.
